

Question:

James decides to run 3 sprints 3 times a week. He runs 60 meters each sprint. How many total meters does he run a week?

Reasoning + Answer:

<think> To find out how many meters James runs a week, I need to calculate the total number of meters he runs in one day, then multiply it by the number of days he runs in a week.

First, I need to find out how many meters James runs in one day. Since he runs 3 sprints a day, and each sprint is 60 meters, I can multiply the number of sprints by the distance of each sprint to get the total distance per day.

Total meters per day = number of sprints * distance per sprint

Total meters per day = 3 * 60

Total meters per day = 180 meters

Now, I need to find out how many meters James runs in a week. I know he runs 3 times a week. So, I need to multiply the total meters per day by the number of times he runs a week.

Total meters per week = total meters per day * number of times he runs a week

Total meters per week = 180 * 3

Total meters per week = 540 meters

</think><answer>540</answer>
