

Question:

Every day, Wendi feeds each of her chickens three cups of mixed chicken feed, containing seeds, mealworms and vegetables to help keep them healthy. She gives the chickens their feed in three separate meals. In the morning, she gives her flock of chickens 15 cups of feed. In the afternoon, she gives her chickens another 25 cups of feed. How many cups of feed does she need to give her chickens in the final meal of the day if the size of Wendi's flock is 20 chickens?

Reasoning + Answer:

<think> To solve this problem , let's first understand what information is given . Wendi provides her chickens with 3 cups of feed for every chicken per day . We know the feeding pattern and amounts for the morning and afternoon feedings . We need to calculate the total number of cups fed in these two times , add the total to find the total feed used , and then figure out how much is left to be given in the final feeding . Given that there are 20 chickens in Wendi's flock , let's carry out the calculation step by step . For every single chicken , Wendi uses 3 cups daily . With her 20 chickens , the initial total for the entire flock is 3 cups * 20 chickens . We know the morning feeding is 15 cups , and the afternoon feeding is 25 cups . So , to find the total used , we first calculate $(15 \text{ , cups } + 25 \text{ , cups })$. After that , we subtract this total from the initial 3 cups * 20 to find the final amount of feed needed in the last meal . </think>

<think> To confirm the math steps :

- 1 . Initial total daily feed for 20 chickens is $(3 \text{ , cups per chicken } \times 20 \text{ , chickens } = 60 \text{ , cups })$.
- 2 . Add the feed used in the morning and afternoon , we get $(15 \text{ , cups } + 25 \text{ , cups } = 40 \text{ , cups })$.
- 3 . Subtract the amount fed already from the initial total to find the required for the final feeding : $(60 \text{ , cups } - 40 \text{ , cups } = 20 \text{ , cups })$. </think>

<answer> 20 </answer>
