

**Question:**

A 17-year-old teenager is brought to the emergency department with severe bleeding from his right hand. He was involved in a gang fight about 30 minutes ago where he received a penetrating stab wound by a sharp knife in the region of the ‘anatomical snuffbox’. A vascular surgeon is called in for consultation. Damage to which artery is most likely responsible for his excessive bleeding?

Answer Choices:

- A. Radial artery
- B. Ulnar artery
- C. Princeps pollicis artery
- D. Brachial artery

**Reasoning + Answer:**

<think>  
To determine the most likely responsible artery for the excessive bleeding , we need to consider the location of the stab wound . The ' anatomical snuffbox ' is a region on the radial , dorsal aspect of the wrist . This location is most closely associated with the radial artery . The radial artery is directly vulnerable to injuries in this region due to its superficial location and proximity to the snuffbox . Therefore , the most likely artery damaged in this scenario is the radial artery .  
</think><answer> A . Radial artery
