

Question:

At birth, the least developed part of the brain is the

Answer Choices:

- A. visual system
- B. thalamus
- C. frontal lobe
- D. brain stem
- E. parietal lobe
- F. cerebellum
- G. cortex
- H. basal ganglia
- I. hypothalamus
- J. limbic system

Reasoning + Answer:

<think> The human brain undergoes significant development and growth post-birth, with different regions maturing at various rates. The most developed part of the brain at birth, the visual system, is fully formed, allowing newborns to detect light and dark and respond to visual stimuli. In comparison, the most developed areas of the brain at birth are primarily the brain stem, which regulates essential life-sustaining functions, and the visual cortex, which processes visual information. The parietal lobe, responsible for processing sensory information and memory, is generally more developed than the other areas listed. The other parts listed, while partially developed, are not entirely formed. Given these facts, the least developed part of the brain at birth would be the more complex and sophisticated regions listed. Based on the choices provided, it must be one of the remaining options, excluding the relatively well-developed areas. To select the correct option, I can analyze the complexity and level of the developmental requirements for the listed regions and correlate that to the provided choices to accurately narrow down which part of the brain is more than likely to be the least developed. The key would be the option with substantial developmental requirements and needs more development over infancy and in initial years and consider major cognitive and motor feats and substantially more brain development hence the answer will be primarily F </think><answer> F. cerebellum </answer>
