

Question:

Every day, Wendi feeds each of her chickens three cups of mixed chicken feed, containing seeds, mealworms and vegetables to help keep them healthy. She gives the chickens their feed in three separate meals. In the morning, she gives her flock of chickens 15 cups of feed. In the afternoon, she gives her chickens another 25 cups of feed. How many cups of feed does she need to give her chickens in the final meal of the day if the size of Wendi's flock is 20 chickens?

Reasoning + Answer:

<think>

Wendi already gave 15 cups in the morning and 25 cups in the afternoon . To find the total feed given , we need to sum the feed in the morning and afternoon . That's $15 + 25 = 40$ cups .

Now , we multiply the total daily feed given by the number of chickens (20) to find how much feed per chicken is needed in one day . We calculate : $40 * 20 = 800$ cups .

To find the total feed needed , it is already given that daily feed per flock is 40 cups divided among three meals . Hence , each separate meal is $40 / 3$ cups for each chicken .

For the final meal , this includes daily feed left after morning and afternoon , i . e . , 800 cups - total feed given in the first two meals , 40 cups per meal for 20 chickens to the 2nd meal i . e . , $25 * 20 = 500$.

To find the feed for the final meal we subtract these from daily total : $800 - 40 - 500 = 260$.

</think>

<answer>

260 </answer>
