

Question:
Which of the following factors is associated with a decreased risk of Alzheimer's?

- Answer Choices:
- A. Being African or Hispanic American
 - B. A lower level of education
 - C. Living in a city
 - D. Being married
 - E. Having a family history of Alzheimer's
 - F. High intake of saturated fats
 - G. Older age
 - H. Eating fish
 - I. Being a smoker
 - J. Drinking alcohol regularly

Reasoning + Answer:

<think>
Several factors contribute to the risk of Alzheimer's disease, but being married is known to have a protective effect. Studies have shown that social engagement and strong social connections, which are often found in marriage, may help reduce the risk of cognitive decline and Alzheimer's. Married individuals tend to have a lower risk of cognitive decline compared to those who are single or divorced. This is possibly due to the increased social support, emotional stimulation, and cognitive engagement that come with being in a committed relationship. Therefore, being married is associated with a decreased risk of Alzheimer's. Other factors such as lifestyle, genetics, and age also play a role, but among the given options, being married is a key factor that reduces the risk of Alzheimer's. So, the correct answer is related to the protective effects of marriage on cognitive health.

</think><answer> D. Being married </answer>
