

Question:
Forceps delivery is done in all except: Answer Choices: A. Mentoposterior B. Deep transverse arrest C. After coming head D. Maternal heart disease

Reasoning + Answer:

<think>### Finding Reasoning Paths : 1 . **Head entrapment and fetal distress** : Assess the risks of forceps delivery in cases where the head may become entangled in the pelvis , leading to fetal distress . 2 . **Mother's heart disease** : Evaluate the impact of maternal heart disease on physical endurance required for a forceps delivery , which can exacerbate cardiovascular strain . 3 . **Entanglement in posterior positions** : Consider the anatomical limitations and challenges posed by posterior positions , particularly mentoposterior , in a forceps delivery . ---### Reasoning Process : 1 . **Head Entrapment and Fetal Distress** : - A forceps delivery is a low-risk procedure when performed by skilled obstetricians . However , it carries risks such as umbilical cord entanglement , vascular compression , and prolapse of the cord . If the fetal head becomes entangled in the pelvis during a forceps delivery , this can lead to fetal distress due to inadequate oxygenation and circulation . 2 . **Mother's Heart Disease** : - Mother's heart disease can impair the mother's ability to withstand the physical strain of a forceps delivery . The procedure requires significant maternal physical endurance , increased venous return , and increased heart output . If the mother's cardiovascular system is compromised , she may not be able to cope with the additional stress , potentially leading to complications such as a cardiac event . 3 . **Entanglement in Posterior Positions** : - Posterior positions , including mentoposterior , pose unique challenges in a forceps delivery . The fetal head's positioning limits the forceps's ability to safely maneuver the head without causing complications . This can increase the risk of umbilical cord entanglement and vascular compromise , making forceps delivery particularly risky in these situations . 4 . **Combination of Factors** : - The risk of fetal distress from entanglement , combined with the maternal cardiovascular strain due to heart disease , suggests that forceps delivery may be contraindicated in these cases . The increased risk of complications necessitates a more conservative approach to avoid harm to both the mother and the fetus . ---### Conclusion : Forceps delivery is contraindicated in cases of maternal heart disease and in posterior positions , such as mentoposterior , due to the high risk of fetal distress and complications . </think> <answer> Maternal heart disease </answer>
 Laterally fixated fin / broadly fixated fin
