

Question:

Among the following, which one is considered as 'pathologic problem' while planning treatment in orthodontics? Answer Choices: A. Tendency of lower jaw and teeth to be behind upper B. Deep overbite C. Minimal attached gingiva in lower anterior region D. Decalcification

Reasoning + Answer:

<think> **Finding reasoning paths: ** 1. Evaluate the nature of the condition - whether it is a pathological issue, a result of genetic/developmental factors, or a treatment-related issue. 2. Assess the impact of the condition on oral health and overall dental function. 3. Consider common orthodontic terminology and classification of dental and orthodontic issues. 4. Determine if the condition is a result of normal anatomical variation or a genuine pathologic process. **Reasoning Process: ** 1. **Nature of the Condition:** The term "minimal attached gingiva" refers to a condition where there is a lack of sufficient connective tissue attached to the teeth, particularly in the lower anterior region. This can be due to developmental factors, genetic predisposition, or possibly environmental factors. 2. **Impact on Oral Health:** Insufficient attached gingiva can lead to increased susceptibility to dental caries, gum recession, and difficulty in maintaining oral hygiene, which are all potential pathological issues. 3. **Orthodontic Perspective:** In orthodontics, "attached gingiva" is a specific term for the connective tissue that directly adheres to the teeth, as opposed to the marginal gingiva, which is the gum tissue at the gingival margin. A "minimal" attached gingiva may indicate a borderline case or a condition that could compromise oral health. 4. **Pathological Consideration:** While the term "pathologic problem" might initially seem generic, in the context of orthodontics, it typically refers to issues that could lead to systemic or severe local health issues, such as significant gum disease, tooth mobility, or infection. The condition of minimal attached gingiva, if severe or contributing to other problems, could indeed be considered pathological. **Conclusion: ** Based on the reasoning, a condition of "minimal attached gingiva" in the lower anterior region could be considered a pathologic problem if it leads to significant issues like gum disease, caries, or compromised oral hygiene. This conclusion aligns with the understanding that insufficient attached gingiva can have negative implications for oral health, making it a concern in treatment planning. </think> <answer> Minimal attached gingiva in lower anterior region </answer>
