

Question:
Forceps delivery is done in all except: Answer Choices: A. Mentoposterior B. Deep transverse arrest C. After coming head D. Maternal heart disease

Reasoning + Answer:

<think>### Finding Reasonable Explanations: 1 . Forceps delivery is a commonly performed delivery method in obstetrics , which uses forceps , a sterile metal instrument used to grab the head of the fetus and pull it out of the birth canal . 2 . Ideally , forceps should only be used when **lying in** , meaning that the baby's head should be positioned fully into the birth canal . In a forceps delivery , the intervention is still active during delivery . 3 . A head-first presentation with a rotated head is not suitable for forceps delivery . Forceps are designed to gently assist the fetal head descent without significant rotation or dislocation . 4 . Forceps delivery is not performed at full cervical dilation because positioning the mother and aligning the forceps requires continued active intervention . At full cervical dilation , passive delivery occurs , which contrasts with the active forceps intervention . ---### Reasoning Process: 1 . **Timing of Forceps Intervention** : - Forceps delivery usually involve positioning the mother in a " flattened " position to better align the fetal head and adjust the angles involved . - The mother's body weight also aids the descent of the fetus . - An inexperienced baby presents significant challenges to a forceps delivery , which requires active forceps intervention during the second stage of labor . - At the beginning of delivery , the fetal head is gently scooped with the right forceps and positioned to enter the birth canal better . - The insertion of forceps happens slightly before complete engagement of the fetal head in the canal ; only the occiput remains outside the vagina . These points collectively confirm that forceps are used before completed delivery . 2 . **Procedure Limitations** : - Forceps were originally intended to help delivery even when obstructions formed hindrances . - Anterior shoulder and posterosuperior fetal parts issues can impede delivery , creating forceps objections for delivery efforts . - Methods like forceps opposition , opposition-handedness , redirection-handedness , and combined opposition-redirection-handedness were designed to adapt to specific fetal part presentations and obstructions . 3 . **Conclusion on Non-Appliance** : - Forceps were devised for anterior-descended or transverse presentation to aid biplane adjustment and overcome bipartite unevenness challenges . ---### Conclusion: Forceps delivery is indeed most effectively employed before completed delivery , aligning with the typical obstetric procedure and considerations. </think><answer>After coming head </answer>
