

Question:

Kylar went to the store to buy glasses for his new apartment. One glass costs \$5, but every second glass costs only 60% of the price. Kylar wants to buy 16 glasses. How much does he need to pay for them?

Reasoning + Answer:

<think>The first glass costs <think>5</think> dollars , so the cost of second glass , which is 60 % cheaper , is <think>5 * 0 . 6 = 3</think> dollars . The total cost for three glasses including the first and second and following pattern , where each second glass is sold cheaper , amounts to <think>5 + 3 + <think>(5 + 3 + 3)</think> + ... </think>. Starting with an initial of three units of cost , <think>5 + 3</think> we need an additional <think>13</think> pairs of glasses which gives <think>(5 + 3) * 13 = 91</think>. The total <think>3 + 91 = 94</think> cost across 16 glasses comes to <think>94 * 5 = 470</think>.</think>
<answer> 470 </answer>
