

Question:

Kylar went to the store to buy glasses for his new apartment. One glass costs \$5, but every second glass costs only 60% of the price. Kylar wants to buy 16 glasses. How much does he need to pay for them?

Reasoning + Answer:

<think>

Kylar's desire is to acquire 16 glasses
in the very first cycle , every 2 glasses give Kylar a glass for free price
as the quantity doesn't reach to 2 glasses mark in the first iteration , the cost calculation shall start
with 16 initial glasses
again because , on first purchase glass of 2 purchasing glasses the price ends up at 0.60 of the first
total payment which has to be accounted for is then 5 times in every purchase
in the start by accounting there are whole 8 packages of 2 glasses (16 / 2 = 8)
each package pricing considering the discount prices is $5 (0.6) + 5$
to find the cost of these 16 glasses the total would be
 $5 * 2$ where 5 is the original cost and 2 is the packages
 $50 * 8$ does the payment occur , taking the packages as to total item pricing
quantity = 16 count to prices
 $5 * 8 = 40$, one pay per for each pair in the next tiers
answering in a cumulated process as $40 * 8$

</think>

<answer>

40

</answer>
