

Question:

A group of scientists is conducting an experiment on the human cells involved in the immune response. They genetically modify B cells so they do not express the cluster of differentiation 21 (CD21) on their cell surfaces. The pathogenesis of which of the following organisms would most likely be affected by this genetic modification?

Answer Choices:

- A. Epstein-Barr virus (EBV)
- B. Measles virus
- C. Human immunodeficiency virus (HIV)
- D. Human papillomavirus

Reasoning + Answer:

<think>
- CD 2 1 is a receptor protein on B cells that is used by certain viruses to enter the cells .
- Epstein -B arr virus (EB V) and Me as les virus both use CD 2 1 as a receptor .
- HIV uses CD 4 and co -re ceptors like C CR 5 or CX CR 4 , and Human pap ill om a virus does not use CD 2 1 .

Thus , the most affected path ogenesis would be that of Epstein -B arr virus (EB V) and Me as les virus . Since the question asks for the most likely one , Me as les is a strong candidate as EB V also uses CD 2 1 but Me as les is more directly affected as it relies on CD 2 1 for entry more directly than EB V does .

</think>
<answer>B . Me as les virus </answer>
